Part 1: Exercise 5b

Load Dataset

The dataset consists of 990 observations and 14 variables.

```
vowel <- read.arff("vowel.arff")
head(vowel, 3)</pre>
```

```

K Means

K-means algorithm works as presented below:

- 1. Choose groups in the feature plan randomly
- 2. Minimize the distance between the cluster center and the different observations (centroid). It results in groups with observations
- 3. Shift the initial centroid to the mean of the coordinates within a group.

- 4. Minimize the distance according to the new centroids. New boundaries are created. Thus, observations will move from one group to another
- 5. Repeat until no observation changes groups

Since M-means is based on distances of among data points, there few different measures it take into account. For example, *Euclidean* distance is the most common method, though we could also use *Manhattan* and *Minlowski* distances as well. Below, present the mathematical formulation of *Euclidean* distance.

$$distance(x,y) = \sum_{i}^{n} (x_i - y_i)^2$$
(1)

Optimal K

One technique to choose the best k is called the *Elbow* method. This method uses within-group homogeneity or within-group heterogeneity to evaluate the variability. Another approach is called *Silhouette*. We will measure within groups sum of squares(variance) and the quality to clusters to determine the optimal value of k. For this, we will install the package *factoextra*.

Elbow

The elbow method is a method used to determine the number of clusters in a data set. It defines clusters in such a way that the total intra cluster variation (total within-cluster variation or total within-cluster sum of square) is minimized. We can formulate it as:

$$\min \sum_{k=1}^{k} W(C_k) \tag{2}$$

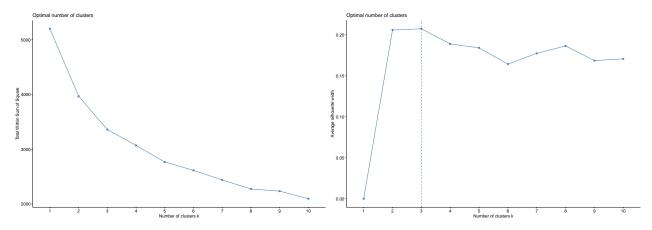

where C_k is the k^{th} cluster and $W(C_k)$ is the within-cluster variation. The total within-cluster sum of square measures the compactness of the clustering and we want it to be as *small* as possible

Silhouette

The average silhouette method measures the quality of a clustering. It determines how well each object lies within its cluster. A high average silhouette width indicates a good clustering. The average silhouette method computes the average silhouette of observations for different values of k. The optimal number of clusters k is the one that maximizes the average silhouette over a range of possible values for k.

Both of the above process can be computed by the following code snippet.

```
set.seed(123)
fviz_nbclust(vowel_drop, kmeans, method = "wss")
fviz_nbclust(vowel_drop, kmeans, method = "silhouette")
```

We see the best value of k for the given dataset is 3.

Add Class attribute

Now, we will add the class attribute to the dataset $vowel_drop$ and will repeat the same process of previous section.

```
vowel_drop_2 <- select(vowel, -1, -2, -3)
unique(vowel_drop_2$Class)</pre>
```

[1] hid hId hEd hAd hYd had hOd hod hUd hud hed ## Levels: hid hId hEd hAd hYd had hOd hod hUd hud hed

We observe that the levels of the column *Class* are 11. Though, it appears that there are duplicates in classes cause of typos, case-sensitivity etc. The unique classes in the dataset are 6. We have found previously that the optimal value of k is 3. We will plot the clusters.

```
k3 <- kmeans(vowel_drop, centers = 3, nstart = 25)
fviz_cluster(k3, geom = "point", data = vowel_drop) + ggtitle("k = 3")</pre>
```

The clusters overlap quite a bit cause of the nature of the dataset. Especially the red and green clusters appear to be misplaced. It does not seem that there is a good correlation among true-clusters and the 3 clusters of k-means.

Classification

In this section we will try to address the same problem from a different perspective. We will try two classifiers (Naive Bayes, SVM) and will measure their performace.

Naive Bayes

##

hid 76 10

The fundamental Naive Bayes assumption is that each feature is independent and equal with each other.

```
library(e1071)
nb_model = naiveBayes(as.factor(Class) ~., data=vowel_drop_2)

modelPred <- predict(nb_model, vowel_drop_2)
cMatrix <- table(modelPred, vowel_drop_2$Class)
confusionMatrix(cMatrix)

## Confusion Matrix and Statistics

                                                              0.92611
                            0.83333
                                                   0.91722
                                                                          0.97167
##
                         Class: hed
## Sensitivity
                            0.84444
## Specificity
                            0.99222
## Pos Pred Value
                            0.91566
## Neg Pred Value
                            0.98456
## Prevalence
                            0.09091
## Detection Rate
                            0.07677
## Detection Prevalence
                            0.08384
## Balanced Accuracy
                            0.91833
```

Accuracy is 86.4% which is better than Naive Bayes. The accuracy of SVM is quite high(rbf kernel not tested) which is expected because the algorithm by its nature is able to draw non-linear decision boundaries. In constrast, KMeans is very sensitive to noisy data.

```

Since the first 3 attributes are categorical data(factors) KMeans is not applicable to them since it is a distance based algorithm.
